Write-up

Flores was one of the more promising freshman arms on Texas' 2025 club but found himself in a diminished role during 2026, struggling to consistently find the strike zone while walking nearly as many hitters as he struck out. After the season he entered the transfer portal looking for a fresh start ahead of his draft year. The profile is built around power velocity and a sinker-cutter combination that can generate weak contact, but the lack of a true putaway offering currently limits the ceiling. At 6-foot-2 and 240 pounds, the frame and delivery point more toward a bullpen future than a starter's workload. Even so, the velocity and underlying traits provide a solid foundation. The delivery is smooth, so perhaps simply getting more work would improve the command. If Flores can regain the strike throwing he showed earlier in his career and develop either the splitter or slider into a reliable chase pitch, there is still a path to a future high-leverage relief role.

The SI shows plus ASR with real arm-side life and flashes above-average depth when correctly located, but the pitch is not consistently playing to its shape. Too many sinkers float into deadzone or leak up in the zone, which neutralizes the run profile and turns it into more of a contact pitch than a damage suppressor. When properly executed at the bottom of the zone, it does generate heavy ground ball contact and soft contact metrics support the raw traits, but the inconsistency in getting to that location limits the present value. The pitch is still a viable foundational offering due to velocity and movement,

but it needs more consistent depth and command towards the bottom third to fully play at the next level. 40/45 pitch

The CT is pretty stock but holds above average velo and gets to plus cut and holds height well through the zone. This looks like Flores's best pitch overall, but poor command led to a .385 average and 0 whiffs as too many cutters were left over the heart of the plate. Yet, the underlying traits suggest better results than the .385 average allowed. The good and late cut on the pitch suggest that it could perform better in the future. Keeping the ball down and gloveside will be the next step. 40/45 pitch

The SL carried below average shape and was inconsistent. Sometimes it showcased as a gyro and other times as a sweepier slider. This pitch is a microcosm for the poor feel that Flores showed this year, with an inability to put in optimal locations and then inconsistent shape. Further, he lacks the feel for spinning the ball with a SL spin rate below average for the collegiate level. 30/35 pitch

The SPL to me is the better of the secondaries from a stuff standpoint, showcasing low spin rates and unpredictable movement at times. On the other hand, Flores was rarely able to throw it near the zone as it registered a 19% zone rate and 15% chase rate. He missed gloveside down to lefties, failing to get the ball moving away with depth causing easy takes as opposed to hesitant ones or chases. When located well, the pitch looked late and had bite to it. The gloveside misses really hamper the ability of a splitter to get whiffs. 40/45+ pitch
