Write-up

Moss is an interesting case for what makes a good college starter, and what breaks through at the pro level. He possesses two plus pitches in a two plane fastball that he spots well and a bugs bunny changeup that is arguably a top 5 offspeed in all of college baseball. He threw a slider as well and was working on a sweeper towards the end of the season. The three pitch mix, and truly just a 2 pitch one at first, worked when he followed senior Saturday arm Michael Barnett but he struggled out of the rotation when Logan Reddemann went down with injury. He gave up 12 earned runs in those six starts, getting through 6+ twice getting 30.2 IP in that time. Now that's a 3.52 ERA but a far cry from the 6 total runs he gave up in his first 11 appearances (34.1 IP). Next year, he is poised to be the Friday night in the UCLA rotation and he looks to establish the fourth pitch to protect the lethal FB CH combination. He is competitive and fluid, giving floor as a near closer level pitcher, but establishing a consistent slider and a 4th show-me pitch can transform him into a true starter at the big league level. The FB is the foundation of Wylan Moss, a ride/run pitch that he can put on both parts of the plate, using the natural ASR from his massive pronation to create a high spin heater. It tilts at about 1:15 so it gets real ASR, but the ride is very present. At the top of the zone, he dominated to RHH where most of his 22 RHH FB whiffs were but he was also able to get CS on the outer half, letting the FB carry over to the plate. There was limited presence on the inner third to LHH and he worked away from them, getting success to a .190 avg against. Velo is closer to above average than plus but his lanky frame

allows him to get up to 7 feet of extension, giving the FB the extra tick of life. He also, with the amount of ASR he gets, creates an interesting horizontal angle to the plate with an average positive horizontal approach, a metric normally reserved for lefties and changeups. The combination of late life, extension, and command show a truly above average pitch, and as he matures into his body he can gain an extra tick of velo. 50/55+ pitch

The SL is a lifted gyro that has more slight gloveside than plus and acts more like a cutter at times when up. When down, it shows late bite but when up, it is more of a floaty cutter. He struggled to get it down at times leaving it more middle gloveside than down gloveside. The zone rate is below average but the misses out the zone are down which presents better than lack of finish results. Gaining feel for the pitch is important for his development as right now it is a third pitch that exists purely to get hitters off the FB/CH. With his feel to pronate through the ball, a hard gyro is a possible shape to reach long term but the current lift slider is a below average shape. 40/50 pitch

The SWP was thrown 4 times but was a development focus for Moss in the summer leading into 2027. 35/35 pitch

The CH is Moss's best pitch and is a slow CH getting 11+ mph difference and 5 inches of induced vertical difference. The pitch has late arm-side life and burrows into the hands of RHH and bites away from LHH. He keeps it down consistently and locates D/A to both sides. To RHH he missed too many CH up in the zone where he got barreled and allowed his homers. When he keeps it down, it is an elite pitch and allowed a total .157 avg on the season and a 35% put-away rate. Truly a special pitch that looks like a UFO crossing the plate. 60/70 pitch
